

A valid level needs exactly 1 player, 4 boxes and 4 goals. Only one of these two can check.

Autoregressive (transformer)

each cell is emitted after the ones before it

state visible to the next decision

boxes placed = 2 of 4 cells left = 61

so it can stop at exactly four

**measured: 87.1% of draws have exactly 4 boxes
mean 3.87 ± 0.34**

One-shot decoder (VAE / GAN)

all 100 cells decoded at once from one latent

state visible to each cell

nothing: cells are independent given z

so it gets the right average, not the right count

**measured: 21.8% of draws have exactly 4 boxes
mean 3.95 ± 1.72 (right mean, wrong joint)**
